SAN LORENZO WASTEWATER MANAGEMENT PLAN PROGRAM STATUS REPORT, 1999-2001

This Status Report on Wastewater Management Efforts in the San Lorenzo River Watershed is a compilation of information from the 1995-98 Program Status Report (March, 2000) and Draft San Lorenzo River Watershed Management Plan Update (March, 2002), with some additional updates of data provided. A more extensive program review is anticipated to be completed by 2005, in conjunction with updating the wastewater management program to conform with statewide regulations for onsite sewage disposal system management, scheduled to be adopted in January of 2004.

Summary of Water Quality Issues in San Lorenzo Watershed

Nitrate and pathogens are the two water quality parameters in the San Lorenzo Watershed that can be affected by wastewater disposal, among other sources.

Nitrate

Nitrate levels in the River are estimated to be 5-7 times above natural background levels (SCCHSA, 1995). At about 0.35 mg-N/l, nitrate levels in the River are well below the safe drinking water standard of 10 mg-N/l. However, nitrate is the limiting nutrient in the River and increased nitrate levels can stimulate biological growth of algae, molds, fungi, and other organisms. This increased biological activity threatens drinking water supply by releasing organic compounds, which cause noxious tastes and odors and produce potentially carcinogenic disinfection byproducts when the water is treated. Localized concentrations of nitrate in groundwater have at times threatened to violate the drinking water standard in areas of Ben Lomond, Boulder Creek, and Scotts Valley.

The San Lorenzo Nitrate Management Plan (SCCHSA, 1995) determined that an estimated 84% of the current nitrate load in the River results from human activities in the watershed. Calculations of relative contributions to present summer nitrate levels in the lower River (at Felton) are as follows:

- Septic Systems in sandy areas	38%
- Septic Systems in non-sandy areas	19%
- Natural sources in sandy areas	12%
- Sewer discharge from B.C. Country Club	10%
- Scotts Valley nitrate plume	9%
- Livestock and stables	6%
- Natural sources in non-sandy areas	4%
- Landscaping/fertilizer use	2%

Approximately 67% of the nitrate in the River during the summer comes from areas underlain by sandy soils of the Santa Margarita Sandstone. A septic system in sandy soils contributes 10-15 times as much nitrate to the River as a septic system in less permeable soils. Nitrogen reduction efforts are most needed and will be most effective in areas with sandy areas.

In some parts of the country, harvesting of timber can cause significant release of nitrate to streams. Several monitoring efforts in the San Lorenzo Watershed have indicated that timber harvests are not

a significant source of nitrate in this area. This is likely due to several factors: the relatively small extent of individual harvests, harvests are not clear-cuts, forest soils in the San Lorenzo Watershed tend to be more clay-rich and hold onto nitrate, and the other sources of nitrate in San Lorenzo tend to be much more significant than any contribution from timber harvests.

Pathogens

0.5 0.4 0.3 0.2 0.1

Presence of bacteria, virus, giardia, cryptosporidium, and other pathogens can make the water unsafe for swimming and require more expensive treatment efforts for drinking water supply. Practically all of the testing for pathogens involves testing for indicator bacteria (total coliform, fecal coliform, E. coli, and enterococcus) that would suggest the possible presence of pathogens from sewage, fecal contamination, or other contamination. Limited testing for pathogens by the City of Santa Cruz has confirmed the presence of cryptosporidium and giardia in the San Lorenzo River. The presence of indicator bacteria, while not necessarily causing illness, causes beaches to be posted with warning signs and significantly impacts recreational opportunity. The frequency of posting of swimming areas in the watershed has declined significantly since the 1970's and the 1980's, as septic systems have been upgraded and better maintained. However, the Rivermouth continues to have consistently high bacteria levels and is permanently posted as unsafe for swimming. Sources of pathogens and indicator bacteria are non-point source urban runoff, failing septic systems, sewer system leaks, pet waste, livestock, encampments, and waterfowl.

There are over 13,000 septic systems in the San Lorenzo Watershed upstream from Santa Cruz. Under current wastewater management programs, the occurrence of septic system failures is relatively low. Since 1986, the wintertime septic failure rate has declined from 5-14% to 1-3%, depending on the area (SCCHSA, 2000). However, during rainfall periods, partially treated sewage which comes to the ground surface from septic failures can be readily washed into ditches, roadways, creeks and then the River. For brief periods after storms and in the early spring when water tables are high, ditches may continue to run, conveying diluted sewage to creeks. During dry periods, sewage from failing septic systems would not reach a waterway unless the failure was right on the banks of the creek. Programs implemented since 1986 have required system upgrades, improved setbacks from creeks and early identification of failures. Summer bacteria levels have shown substantial improvement, and the River generally meets standards for safe swimming at all areas upstream from Santa Cruz. Subsurface contribution of bacteria from apparently functioning septic systems has not been found to occur in the San Lorenzo Watershed (SCCHSA, 1989). Dry season bacteria in the upstream areas are most likely from nonspecific urban sources. The highest levels of indicator bacteria are consistently observed in the more dense urban areas of Santa Cruz and Scotts Valley, which are sewered, indicating most of the bacterial contamination is more related to urban runoff than septic systems. Bacteria levels drop substantially as the River flows out of the suburban areas and through the State Parks or other low-density areas.

Livestock operations are also a potential source of bacterial contribution during storm periods. It is estimated there may be some 400-600 head of livestock kept in the watershed, primarily horses in commercial stables and small homeowner operations. Runoff from paddock areas, trails and manure stockpiles during storms can contribute elevated levels of fecal coliform, Cryptosporidium, and other organisms. Except where animals are allowed into creeks, stables are not a significant source of microbiologic contamination during nonstorm periods. County Environmental Health has had success with encouraging improvement of runoff and manure management at many of the larger operations. However, additional effort is needed.

As a part of the San Lorenzo River Watershed Management Plan Update, the County conducted extensive testing in the lower River area from 1995 through 1997 to better assess the sources of high bacteria in the urban reach of the River. The work found consistently high levels of bacteria downstream from the confluence with Branciforte Creek, which originate from storm drain discharge to the River and Branciforte Creek, as well as the concentrations of waterfowl that congregate in that area. Although the storm drains typically have very high bacteria levels, their dry weather flow is generally light and intermittent. High levels of bacteria in storm drains originate from decaying organic material (including garbage, leaves, and pet waste), occasional sewage spills, and possible subsurface leakage of sanitary sewer systems. Sewage leaks have been confirmed in several storm drains and subsequently corrected, resulting in a decline in bacteria levels in those drains. Leakage may persist in some drains. Since the 1997 sampling, the sewer lines in the vicinity of Branciforte Creek were upgraded and bacteria levels from the Creek have declined significantly. However, the general nonspecific urban contamination keeps the bacteria levels elevated well above standards for safe swimming. Storm sampling of ditches and gutters with no likely sewage influence frequently yielded high levels of indicator bacteria. It has not been confirmed whether pathogens are also present.

Water quality sampling using the four standard bacteria indicators was coupled with a health risk survey of persons in the water to determine the health risk of swimming in areas adjacent to the San Lorenzo River mouth as well as other areas designated as swimming/surfing areas. The health risk

survey showed that there are generally low levels of indicator bacteria producing a good quality swimming water in the beaches adjacent to the mouth of the San Lorenzo River as well as upstream of the City of Santa Cruz in the San Lorenzo River. While the safe swimming standard was almost always exceeded at the mouth of the river only one person out of the 165 persons interviewed that had been swimming or wading in that area became ill. During the study, a total of 1325 people were interviewed at all areas. Eleven cases of illness from swimming were reported.

Status of San Lorenzo Wastewater Management Program

The San Lorenzo Wastewater Management Program has been implemented by the Santa Cruz County Environmental Health Services since late 1985 and was formalized through the adoption of the San Lorenzo Wastewater Management Plan by the County Board of Supervisors and the California Central Coast Regional Water Quality Control Board in the spring of 1995.

The program provides for management and improvement of approximately 13,500 individual onsite sewage disposal systems in the San Lorenzo River Watershed, which have historically contributed to elevated nitrate and pathogen levels in the River. Proper septic system functioning has been challenged by age of systems, small lot size, high winter groundwater levels, steep slopes, close proximity to waterways, and common occurrence of clay soils or excessively drained soils. The Wastewater Management Program has sought to overcome these constraints through water quality monitoring, system inspection, upgrade of systems to effective standards, public education, and tracking of system performance. Activities within the main elements of the Wastewater Plan are summarized in Table 1 and described briefly in the following sections.

Table 1: Summary of Wastewater Management Activities in the San Lorenzo Watershed, 1986-2001

Details are presented in Table 2.

Evaluation of Existing Onsite Sewage Disposal Systems

Over 12,000 parcels have been inspected, and over 80 boreholes or shallow monitoring wells have been installed to evaluate soil and groundwater conditions. Data on inspection results, pumping history, septic system characteristics, and site characteristics has been entered into a computerized database for 10,500 of the 13,500 septic systems in the Watershed. This information has been combined with data from water quality monitoring to evaluate the current performance and the potential for continued use of individual onsite disposal systems in various communities of the Watershed. Despite the constraints present, the large majority (at least 85%) of the systems evaluated were found to be functioning well, and it expected that all but about 10% can ultimately be upgraded to meet current standards using conventional technology. The remainder will likely require use of alternative systems or nonconforming systems with a higher level of oversight.

Disposal System Improvements Completed

Minimum standards for septic system repairs were established by ordinance in 1993, and were strengthened further in 1995, pursuant to the adopted Wastewater Management Plan. At least 3000 systems have been upgraded under permit between 1986 and 2001, with 700 upgrades completed in 1999-2001. The number of system repair applications is currently about 300 per year, an increase of 50% since the beginning of the program. The impetus for system upgrade has been: independent property owner initiative (66%), building remodel (9%), loan inspection (11%), complaint investigation (5%), and inspections done under the Management Plan (9%). In 1999-2001, 92% of the major system upgrades were able to meet the requirements for a standard conventional system, 5% used alternative systems, and 3% were approved nonconforming systems that did not full meet standards. At the end of 2001, 130 alternative systems had been installed in the Watershed: 24 mounded bed systems, 4 at-grade systems, 14 sand filters, and 88 other enhanced treatment units. In the year and a half since 2001, another 40 systems have been or are in the process of being upgraded using alternative technologies.

Notes for Table 2:

- 1. For 1986 1991, complete inspection records are available only for surveys. After 1991, inspections include: surveys, rechecks, complaint investigations, and loan inspections. For repair actions, records may be inconsistent prior to July, 1991, when systematic data entry began. Pumping records are good after Sept., 1988, when submittal of pumping reports became mandatory.
- 2. Numbers of problems under inspections, and total failure rates (unless otherwise indicated) are the total number of leachfield failures and greywater discharges for that year divided by the total number of inspections for that year. Under each type of inspection, the percentage of problems found during that type of inspection is also indicated for each year.
- 3. Under tank pumping, the area failure rate is the number of failures, divided by the total number of parcels in the study area.
- 4. Number of repairs is the number of repair permits applied for in that year. Repair figures for 1986 and 1987 also include other repair activities that do not require a permit.

Inspection and Maintenance

Inspection and maintenance activities consist of County inspections, public education, private pumping activities, and management activities by homeowners. Frequently septic problems have been corrected through improved system management by the property owners. System upgrades and improved management have resulted in a significant decline in failure rates from 5-14% during the initial inspections of Class I areas to 1-3% during reinspections in 1995, and 1-5% during reinspections in the wet year of 1997. Failure rates have continued to decline (Figure 5).

Figure 5: Observed Septic Failures During Parcel Surveys in the San Lorenzo Watershed

Evaluation of Potential for Community Disposal Systems

The Management Plan calls for an evaluation of the potential for use of community disposal systems for areas where there are severe constraints for meeting current standards using conventional septic systems. Under this program, community disposal alternatives have been explored for parts of Boulder Creek, Brook Lomond, Ben Lomond, Glen Arbor, and Felton. For all areas, community disposal systems were found to be less cost-effective than use of individual systems (including alternative systems) and were found to be unaffordable without some kind of grant funding. A community disposal system could be considered for downtown Boulder Creek, which might be eligible for economic development grants since constraints to standard sewage disposal is limiting expansion of the business district. A community disposal feasibility study has been completed for 900 parcels in the Greater Pasatiempo area, in the lower part of the Watershed, and a sewer project is currently being pursued for that area.

New Development

Any new development served by septic systems, which is the majority of the Watershed, must fully meet current standards, including a one acre minimum parcel size, regardless of the date of parcel creation. This requirement was implemented in 1983 in response to State direction to prevent an increase in cumulative impacts from septic systems. Expansion or remodel of existing development does not need to meet the minimum parcel size, but other standards must be met. Expansion of existing development provides a good trigger to bring older systems up to current standards. Over 63 septic system repairs were related to building remodels (almost 10% of the total repairs).

Water Quality Monitoring

An average of about 1000 water samples per year are currently being collected to measure trends in water quality and identify problem areas. Both nitrate and bacteria levels are significantly elevated above natural background levels in the River and many of its tributaries. Although there have been episodes of bacterial contamination from individual septic system failures, much of the bacteria contamination seems to be related to nonspecific nonpoint contamination in the relatively dense urban areas. Most of the nitrate increase is attributable to septic systems, particularly in sandy soils. There have been significant localized improvements in bacteria levels, and there appears to be an improving trend in bacterial levels at most stations since 1996. Nitrate levels and loading in Boulder Creek and the River north of Ben Lomond declined significantly as a result of upgrades of the Boulder Creek Country Club (CSA 7)Treatment Plant.

Program Administration and Financing

The annual budget for countywide wastewater management activities is about \$110,000, with an additional \$215,000 for activities specific to the San Lorenzo. (Roughly 60% of the parcels in the county with septic systems are located within the San Lorenzo Watershed.) These budget figures do not include permit processing activities. The program is funded primarily by annual service charges collected from property owners with septic systems. Since 1996-97, the countywide service charges have been \$6.90 per parcel, with an additional \$18.56 per parcel paid by property owners in the San

Lorenzo Watershed. In late 1995, the State Water Resources Control Board approved the County's request for \$2.2 million from the State revolving Fund to set up a loan program to facilitate septic system repairs. This program was available summer of 1998, but for the past several years has been suspended pending an update of procedures with the state to make the program more usable. Only one loan was made under the old program.

San Lorenzo Nitrate Management Plan and Nitrate TMDL

The San Lorenzo Nitrate Management Plan was developed to address all major sources of elevated nitrate in the River. A grant was obtained under Section 205j of the Clean Water Act to investigate the impacts of nitrate on algae growth and water supply, to determine the primary sources of nitrate in the watershed, and to evaluate various alternatives for nitrate reduction. The Plan includes a watershed nitrate budget, which was used to calculate resulting nitrate levels in the River under different scenarios. The adopted Plan represented a balance between cost and available technology and the need to reduce nitrate levels by a moderate amount in order to reduce potential threats to drinking water quality and recreation. The San Lorenzo Nitrate Management Plan was adopted by the County and State in 1995. The Plan findings and recommendations also formed the basis for the Nitrate TMDL (Total Maximum Daily Load Plan) that was adopted by the Central Coast Regional Water Quality Control Board in 2000.

The recommended nitrate management plan provides for implementing the most cost-effective measures to achieve the desired level of nitrate reduction. The plan provides for limiting increased nitrate release from new or expanded development in sandy soils, and gradually reducing nitrate discharge from existing sources as public and private funds become available and reduction technology improves. Implementation of the recommended policies will provide for a 15-20% reduction in current nitrate levels over the next 10 years, with a further reduction of 10% in the following 10 years. The following measures were recommended (the status of implementation is shown in parentheses):

Manage Wastewater Disposal for Nitrogen Reduction

- 1. Maintain the existing requirement of a one acre minimum parcel size for new development served by septic systems in the San Lorenzo Watershed (Ongoing)
- 2. Implement improved wastewater disposal management through the San Lorenzo Wastewater Management Plan (Ongoing).
- 3. Complete ongoing efforts to improve treatment procedures at Boulder Creek Country Club Treatment Plant to reduce nitrate discharge by using wastewater reclamation on the golf course. (Construction was mostly completed by 1997. The treatment process was then refined and fully operational by May 1998. The improvements provide for wastewater reclamation on the golf course much of the year, with treatment for nitrogen removal at other times. These improvements should ultimately reduce the amount of nitrate in Boulder Creek and in the River between Boulder Creek and Ben Lomond by about 75%. Reductions beginning in 1998 appear to be substantial.)
- 4. Maintain the new requirement for shallow leachfields for new and repaired septic systems (less than 4 feet in sandy areas, and 4-6.5 feet in other areas). (Ongoing)

- 5. Implement enhanced technology for at least 50% nitrogen removal for septic system in sandy soils:
 - a. Require septic systems serving new or expanded uses in sandy soils to install enhanced treatment measures which will reduce nitrogen discharge by at least 50%. (Implemented August, 1995; existing systems to be upgraded at the time of major remodels (projected rate of 1.2% (20 systems) per year).)
 - b. Encourage the use of nitrogen removal methods for any onsite disposal system which will use a nonstandard system. (Estimated 20 upgrades per year.)
 - c. Continue to evaluate new onsite wastewater disposal technology for nitrogen reduction to identify more cost-effective measures. Require higher levels of nitrogen removal if measures become available that are more cost-effective than sand filters.
 - d. Apply for State revolving funds and other funds to develop a funding source to assist property owners in repairing their systems to provide enhanced treatment. (Revised program to be implemented July 2003, with an estimated 40-100 upgrades per year thereafter.)
 - e. When more cost-effective technology and/or funding assistance becomes available, require all onsite system repairs in sandy areas to utilize enhanced treatment for nitrogen removal. (Implementation deferred, pending more inexpensive technology.)
- 6. Require all large onsite disposal systems which serve more than 5 residential units or dispose more than an average of 2000 gallons per day to utilize enhanced treatment to reduce nitrate discharge by at least 50%. Installation of such measures for existing systems shall be required at the time of system repair or upgrade. (Estimated 1-2 upgrades involving approximately 5000 gallons per day per year.)
- 7. Require all new or revised waste discharge permits and all new development projects in the San Lorenzo Watershed to include nitrogen control measures consistent with this Nitrate Management Plan. (County staff has worked with staff at the Regional Board to include nitrogen reduction requirements in new or amended waste discharge permits. This was included in the permits for expansion of the Mount Hermon Association system, the Boulder Creek Country Club system, and the San Lorenzo Valley High School system.)

Livestock Management for Nitrogen Reduction

8. Continue to work with stable owners and develop a new ordinance requiring practices to reduce nitrate discharge: cover manure piles, maintain manure piles and paddock areas at least 50-100 ft from streams or drainageways, direct drainage away from paddock areas, and provide other measures as necessary to reduce discharge of nitrate, sediment, and contaminants. (Ongoing, after meetings with stable and horse owners, it was decided to pursue an approach of education, technical assistance, and voluntary compliance. A grant funded effort by the Resource Conservation District got underway in 2001 and was completed in early 2003.)

Land Use Regulations for Nitrogen Reduction

9. Maintain current density restrictions requiring 10 acres per parcel for new land divisions and

other protective measures for groundwater recharge areas.

- 10. Maintain current regulations on erosion control, land clearing, and riparian corridor protection.
- 11. Do not approve new land use projects within the San Lorenzo Watershed which will increase the discharge of nitrate to groundwater or surface water by more than 15 pounds of nitrogen per acre per year from the project area.

Ongoing Monitoring of Nitrogen Sources

- 12. Monitor the Scotts Valley nitrate plume, and identify potential ongoing sources of nitrate. Work with the City of Scotts Valley and property owners for reduction of nitrate discharge from Scotts Valley, if feasible. (Ongoing monitoring, implementation of potential control measures in 2005, if necessary and feasible).
- 13. Continue to monitor nitrate levels in surface and groundwater. Reevaluate implementation of more stringent control measures if summer nitrate levels in the River have not declined by at least 15% by 2010. (Ongoing monitoring, reevaluation in 2010).
